Closed-loop control compares the feedback position from the feedback device to a desired position. This error is multiplied by a proportional gain — a ratio that converts the error in position units to output in volts or milliamps. The greater the error, the higher the output must be to correct the error.

The closed-loop controller is required to change its gains on-the-fly as the valve shifts between high-and low-gain regions. In theory, this valve linearization (compensation for the varying gains as a function of the control signal) can be done within the motion controller, using a look up table or a specific formula.
