A soil is said to be elastic when it suffers a reduction in volume (or is changed in shape and bulk) while the load is applied, but recovers its initial volume immediately the load is removed. The most important characteristic of the elastic behaviour of soil is that no matter how many repetitions of load are applied to it, provided that the stresses set up in the soil do not exceed the "yield stresses" the soil does not become permanently deformed.

### Elastic Modulus Values for Various Soil Types

This paper focuses on procedures for estimating modulus values for soils that are useable with simple elastic solutions and linear finite element analyses for stresses and deformations. Relationships among Young's modulus, shear modulus, constrained modulus, and bulk modulus are defined so that correlations for any of these various measures of soil stiffness can be adapted to the purpose at hand.

The charts developed herein provide solutions of n under different column spacing (i.e., de / dc ratio), ratios of column to soil moduli (Ecolumn / Esoil), and friction angles of the stone column. Step 2 – Assess the influence of the compressible base soil on n, based on elasticity by the following equation: (18.4) n = n max x r

The depth of the vertical extension of the model below the footing should be sufficient to allow for a deep half-space soil medium and eliminate the effect of stress disturbance from the footing, which is known to be about 4r o for circular footings (reaching 10% of surcharge) in accordance with the well-known elastic Boussinesq solution.

Actually, much like any other material, soil exhibits both elastic and plastic deformation under stress. Elastic (reversible) deformation occurs below a certain threshold and returns to the original shape when stress is removed, whereas plastic (irreversible) deformation occurs after that threshold. To understand such behavior we need to account for two parameters from soil mechanics: the optimum water content (OWC) and soil load bearing capacity (LBC).

Elastic modulus of soil is the parameter and the measure of stiffness of soil. Sometimes, it is also termed as Young's modulus. It is found by dividing the stress by strain taken inside the range of clay soil's elastic behavior.
